Motivation

Leveraging knowledge to design machine learning despite the lack of data using Transfer Learning.

In recent years, considerable progress has been made in the implementation of decision support procedures based on machine learning methods through the exploitation of very large databases and the use of learning algorithms. In the industrial environment, the databases available in research and development or in production are rarely so voluminous and the question arises as to whether in this context it is reasonable to use machine learning methods. This talk presents research work around transfer learning and hybrid models that use knowledge from related application domains or physics to implement efficient models with an economy of data. Several achievements in industrial collaborations will be presented that successfully use these learning models to design machine learning for industrial small data regimes and to develop powerful decision support tools even in cases where the initial data volume is limited.

Leveraging knowledge to design machine learning despite the lack of industrial data.

Thanks to the Industrial Data Analytics and Machine Learning chair,

Motivations / Transfer methods / Applications & Numerical results / packages

Data Sources & several Successes of "ML/IA" models

▶ Imagenet relied on a huge database.
14.10^6 labeled images, 10^3 **categories**,
available for object detection and
image classification at a large scale,
... "quite expensive" labeling effort.

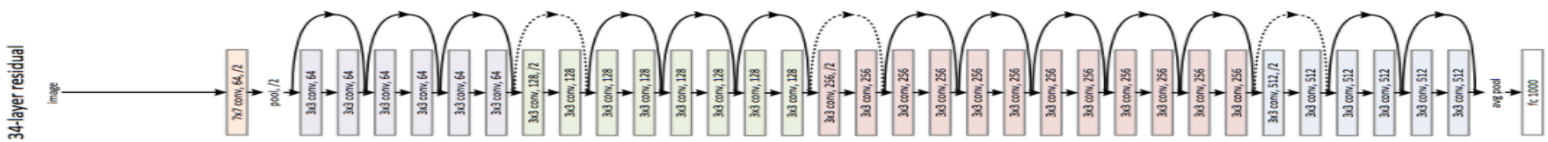

FIGURE – Convolutional Neural Network for image classification (credit :Resnet)

Top-performing deep architecture are trained on massive amounts of labeled data.

▶ DeepL relied on Linguee hudge data base.
Traduction of 1 M of words in one second

▶ Plant Net to recognize plants.

Classical framework for Supervized learning

1. Input/ output (X, Y) (Features, labeling set).
   Ex : $X \in \mathbb{R}^d$, ...$Y \in \mathbb{R}$, ...$Y \in \{0, 1\}$...
2. Data set. $S = \{(x_i, y_i)\}_{i=1}^m \sim \mathcal{D}^m$ a learning/training sample of m iid pairs.
   with $\mathcal{D}$ an unknown joint probability distribution on the product space $X \otimes Y$
3. Model $\mathcal{H} = \{h_\theta | h_\theta : X \to Y\}$ a hypothesis class, θ parameter
   classifiers or regressors depending on the nature of Y.
4. Loss function $\ell(y, h_\theta(x))$ providing a cost of $h_\theta(x)$ deviating form the true output $y \in Y$.

The best hypothesis is the one that minimizes the true risk, consequently, generalizes well :

$$R_{\mathcal{D}}{}^{\ell}(h_\theta) = \mathop{\mathbb{E}}_{(x,y)\sim\mathcal{D}}[\ell(h_\theta(x), y)]$$

The goal of learner consists of finding a good hypothesis function $h_\theta \in \mathcal{H}$ that captures in the best way possible the relationship between X and Y.

$$h^{\text{opt}}{}_\theta = \arg\min_{h_\theta} R_{\mathcal{D}}{}^{\ell}(h_\theta)$$

In pratice : Empirical risk, large training sample, regularisation, sparsity,...

Motivations

Motivation 1. ML for Automatic Elderly fall detection.

Objective.
The Tarkett Floor in motion application tends to detect automatically falls based on sensor information and then trigger an alarm if necessary.

From a first Proof Of Concept (POC) to deployment :

1. Data. As it is not possible to gather large data base with falls of elderly people, a first supervised data base is created with young volunteers containing fall / no fall events.
2. Predictive models. POC to choose and evaluate the performance of a ML model to detect fall on previous data (performances ? true detection, false alarm...).
3. Transfer learning. How to transfer the previous model for elderly care...to a new population given few labeled data ?
4. Budgeted learning. ... and what about in a real environment...

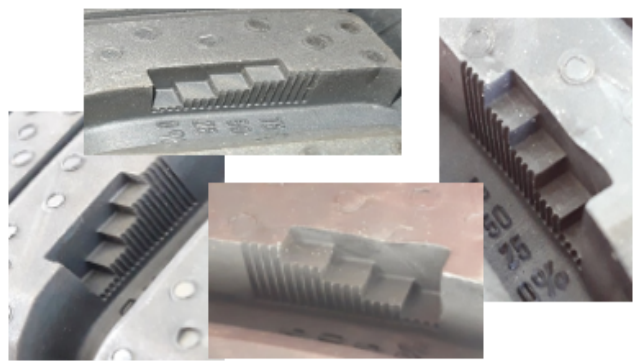
[Minvielle et al., 2017], [Minvielle et al., 2019], [Mounir et al., 2021]

Motivation 2. ML for Automatic tire wear detection

IdF AI IdF Challenge, 2019 organized by the IDAML chair with Michelin collaboration

Industrial objectives :
Designing an application for the
1/ detection and localization in an image
of a "new generation" wear indicator
2/ Estimation of the wear level

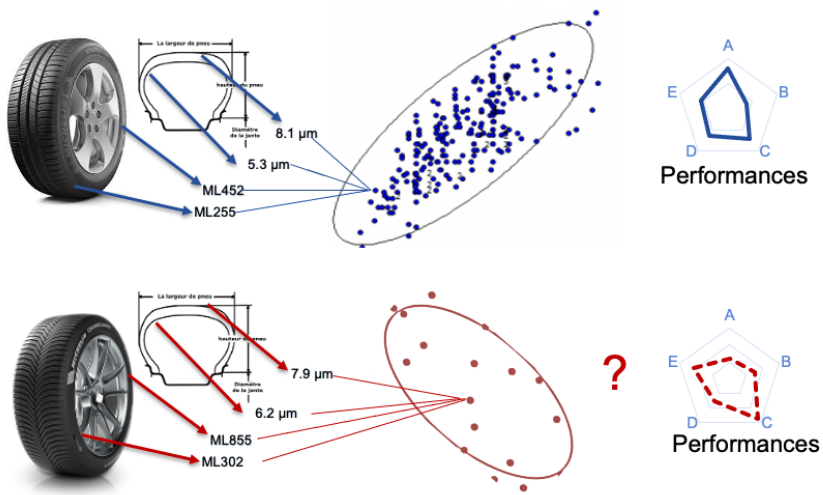
Data base : 1000 tire images with
-various tire views,
-different lighting conditions,
-with and without wear indicator (4 levels).
Learning : 500 images
Blind Evaluation : 500 images.



Motivation 3. ML for Product Design.

Industrial application in collaboration with Michelin, EDF

- New products are regularly manufactured with a long and costly development.
- Relative small data sets are gathered during the development of products as characteristics (color, shape, weight...) and performances.



Is-it possible to predict the performances of a new tire line given data previously gathered from **other** lines ?

[Richard et al., 2021], [de Mathelin et al., 2021]

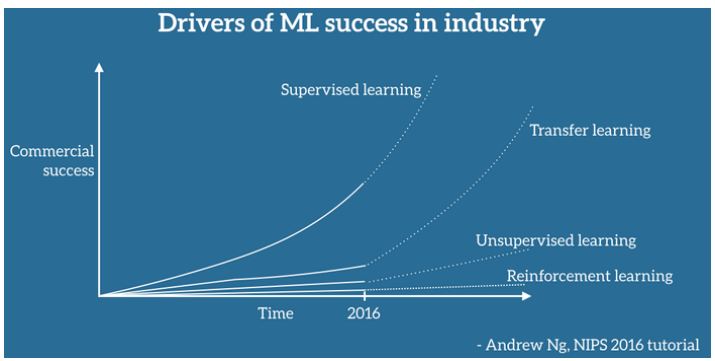
Machine Learning in the industry

Main observations :

- Often small, moderate, evolving database. Ex. manufacturing process.
- Few or not labeled data. Ex. Few production defaults.
- labeled-data is often difficult and time-consuming to acquire.
  Ex. Experimental design to help selecting costly observation outputs.
- In many real-world applications, historical (training) data and newly collected (test) data may often exhibit different statistical characteristics.
- In many ML scenarios, training and test samples are supposed to be generated by the same (unknown) probability distribution.
- Needs for monitoring and diagnosis based on machine learning (ML) .
- Makes sense to re-use knowledge gained form related but distinct datasets.

Need of Transfer Learning, domain adaptation, few shot learning...

Transfer learning : the model can be pre-trained on data from a specific domain and then adapted to meet needs of a given task.



Transfer learning

Transfer learning in industry.

The Transfer learning framework

- **Data collections : Source & Target**
  1. **Source data** $\mathcal{S}$.
     $X_{\mathcal{S}} \otimes Y_{\mathcal{S}}$ the source input and output spaces associated with $\mathcal{S}$
     $\mathcal{S}_X$ the marginal distribution of $X_{\mathcal{S}}$, $t_{\mathcal{S}}$ the source learning task
  2. Target data $\mathcal{T}$
     $X_{\mathcal{T}} \otimes Y_{\mathcal{T}}$ the Target input and output spaces associated with $\mathcal{T}$
     $\mathcal{T}_X$ the marginal distribution of $X_{\mathcal{T}}$, $t_{\mathcal{T}}$ the Target learning task

  Δ Source and Target data are not drawn from the same distribution.
- **Focus** on the Target Risk. $R_{\mathcal{T}}{}^{\ell}(h) = \mathbb{E}_{(x,y)\sim\mathcal{T}}[\ell(h(x), y)]$ with ℓ the loss function.
- **Supervised data or calibrated Model** available for the source domain (enough data).

Transfer learning aims to improve the learning of the target predictive function :
$f_{\mathcal{T}} : X_{\mathcal{T}} \to Y_{\mathcal{T}}$ for $t_{\mathcal{T}}$ using knowledge gained from $\mathcal{S}$ where $\mathcal{S} \neq \mathcal{T}$

$\mathcal{S} \neq \mathcal{T}$ (joint distributions) implies several cases :

- $\mathcal{S}_{\mathcal{X}} \neq \mathcal{T}_{\mathcal{X}}$ i.e. $X_{\mathcal{S}} \neq X_{\mathcal{T}}$ (spaces) or $\mathcal{S}_X(X) \neq \mathcal{T}_X(X)$ (laws) or
- $t_{\mathcal{X}} \neq t_{\mathcal{T}}$ (i.e. $Y_{\mathcal{S}} \neq Y_{\mathcal{T}}$ (target task) or $\mathcal{S}(Y/X) \neq \mathcal{T}(Y/X)$ (conditional law)

... Seems to be a hard problem...
Success stories ?... Theoretical guaranties ? Assumptions ?, Negative transfer ? ....
Answers to the industrial partners.... open source algorithms...

Illustration : Need of Transfer for Learning Machine

Transfer learning aims at providing ML models with a good generalization capability on a **Target domain** (same domains, different domains).

EX. Classical ML framework.

Same Domains & same regression task

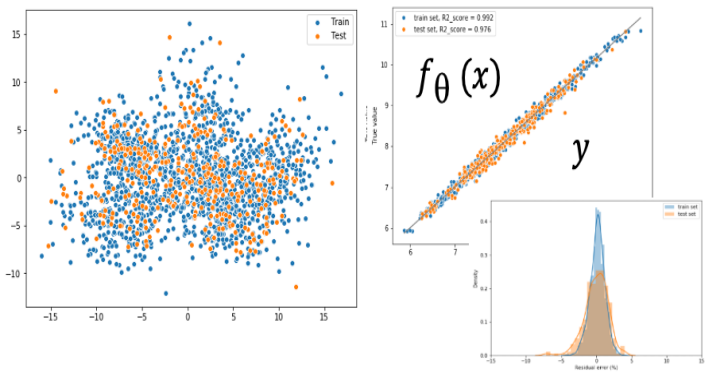


FIGURE – High Prediction capability.

EX2 : Transfer learning framework

Different Domains & same regression task. with covariate-shift assumption

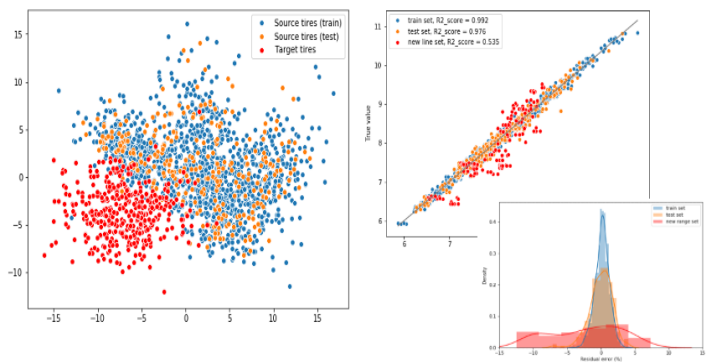

FIGURE – Low Prediction capability.

Transfer Learning & Domain adaptation Methods

Potential approaches to transfer knowledge from Source to Target domain.

- **Model-based.** Transfer the model parameters learnt on the source data to the target model.
  - Train model available, not necessary the source data- .
- **Feature-based.** Find a new representation space to bring feature spaces closer.
  -Source and Target Input data available-.
- **Instance-based.** Re-weight the source samples to bring the distributions closer.
  -Source and Target Input data available-.

Theoretical guarantees ?

For exemple on the Target Risk given the source risk.

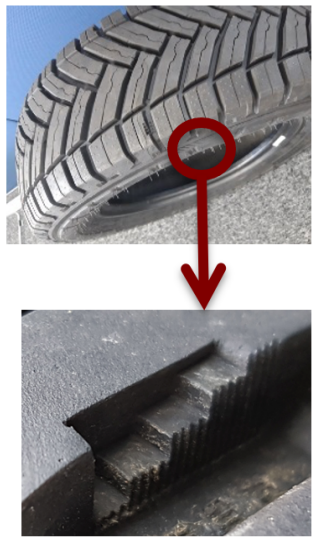
Exemples of Industrial needs and success stories.

- **Model-based :** Image based tire wear estimation based on Deep architecture (Michelin) (Resnet...), Automatic fall detection based on decision trees/ RF (Tarkett).
- **Feature-based :** Domain adversarial neural networks (EDF, Michelin)
- **Instance-based :** Multi-source domain adaptations for Product design (Michelin) or Electricity prediction (EDF)

Transfer learning
Model-based

Model-based Transfer learning. Ex1 : deep N

Industrial Image classification
Automatic tire wear detection, IdF AI Challenge, 2019. Data base :

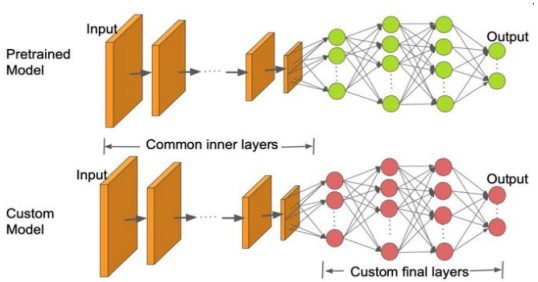


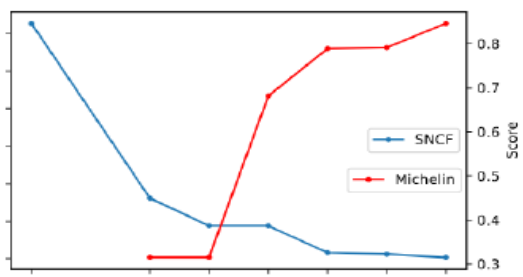
1000 tire images with various tire views, different lighting conditions, with and without wear indicator.
500 images for learning/ 500 images for a blind evaluation.

Two following questions were addressed :
1/ detection and localization in an image of a "new generation" wear indicator
2/ Estimation of the wear level

Development based on Transfer learning

Poor performances obtained with trained model using only the tire data base (20%).
A source pre-trained model (RetinaNet, Yolo...) is used by the candidates (final perf 85%).



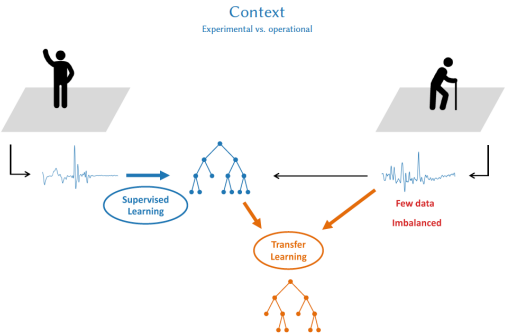


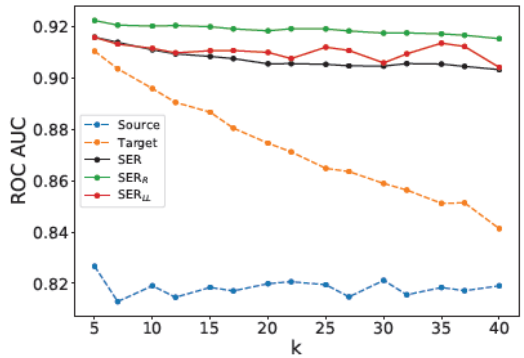
Predicted Class	True Class				
	N/I	25%	50%	75%	100%
N/I	215	0	0	0	2
25%	1	31	2	0	0
50%	0	9	32	1	3
75%	1	0	7	53	8
100%	0	0	0	5	59

FIGURE – Pre-trained model, first frozen weights (credit learnopencv.com)

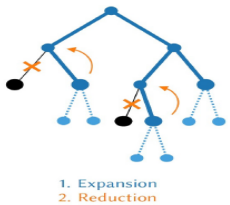
Model-based Transfer learning. Ex2 : decision trees

Fall detection. Strong benefits for transfering knowledge from Source to Target :



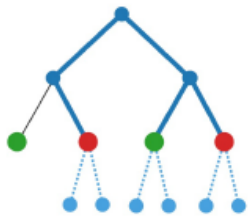


Segev et al. 2017.
SER : Structure Expansion and Reduction



- Idea : train on source domain, extend on target domain the actives nodes, then cut the inactives edges.

SER has to be adapted to take into account class imbalance (few falls) with conditional reduction [Minvielle et al., 2019]



- Expansion left unchanged
- Reduction constrained

SER$_R$	SER$_{LL}$
If node is of minority class, then no pruning	If node is of minority class **and** still significant considering Target **and** $R_L > 0.5$, then no pruning

- Idea : preserve nodes form minority class

Transfer learning
Feature-based

Feature-based TL.

Deep network to confuse source and target input feature data...
Domain Adversarial Neural Networks. [Ganin and Lempitsky, 2015].

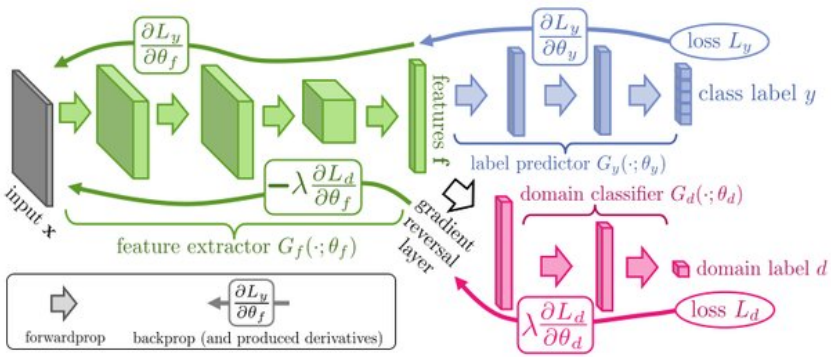


FIGURE – credit [Ganin and Lempitsky, 2015].

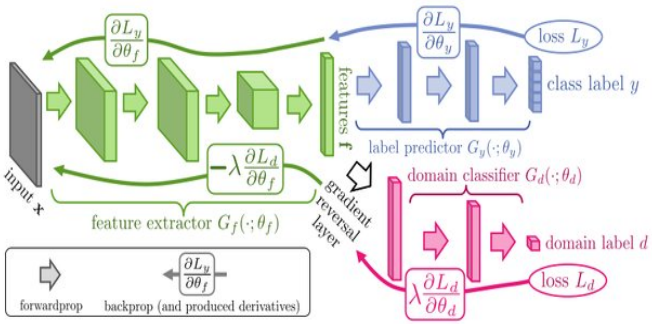
DANN : A neural net architecture and an optimization process to solve both

1. Supervised Task based on Source data to learn the model using an iid sample $\{(x_1, y_1), ..., (x_n, y_n)\} \sim (P(X, Y))^n$, $\hat{h} = \arg\min_{h\in\mathcal{H}} \sum_{i=1}^{n} \ell(h(x_i), y_i)$
2. Unsupervised Domain Adaptation using Source and Target inputs to minimize a distance characterizing the domain divergence.

Feature-based TL.

Domain Adversarial Neural Networks.

[Ganin and Lempitsky, 2015]



Source obs i : $(x_i, y_i, d_i = 0)$
Label obs i : $(x_i, d_i = 1)$
L_y/ L_d : label/ domain loss.
Optimization criteria :

$$E(\theta_f; \theta_y, \theta_d) = \sum_{\substack{i=1\dots N \\ d_i=0}} L_y(G_y(G_f(x_i;\theta_f);\theta_y), y_i) - \lambda \sum_{i=1\dots N} L_d(G_d(G_f(x_i;\theta_f);\theta_d), d_i)$$

The backpropagation optimisation procedure aims to compute the parameters $(\theta_f; \theta_y, \theta_d)$ such that

$$(\hat{\theta}_f; \hat{\theta}_y) = \arg\min_{\theta_f, \theta_y} E(\theta_f; \theta_y, \hat{\theta}_d)$$

$$(\hat{\theta}_d) = \arg\max_{\theta_d} E(\hat{\theta}_f; \hat{\theta}_y, \theta_d)$$

Stochastic updates with learning rate μ

$$\theta_f \leftarrow \theta_f - \mu[\frac{\partial L_y^i}{\partial \theta_f} - \lambda \frac{\partial L_d^i}{\partial \theta_f}]$$

$$\theta_y \leftarrow \theta_y - \mu \frac{\partial L_y^i}{\partial \theta_y}$$

$$\theta_d \leftarrow \theta_d - \mu \frac{\partial L_d^i}{\partial \theta_d}$$

Theoretical setup for domain adaptation

BenDavid et al. introduced in 2006 the $\mathcal{H}$-divergence for 01 loss function, in the setting of binary classification ($\ell_{01}(h(x), y) = 1$ if $h(x) = y$; otherwise 0)

- Given two domain distributions $\mathcal{D}_S^X$ and $\mathcal{D}_T^X$ over X, and a hypothesis class $\mathcal{H}$, the $\mathcal{H}$-divergence between $\mathcal{D}_S^X$ and $\mathcal{D}_T^X$ for classification is defined by :

$$\mathrm{d}_{\mathcal{H}}(\mathcal{D}_S^X, \mathcal{D}_T^X) = 2 \sup_{h \in \mathcal{H}} \left| \Pr_{x \sim \mathcal{D}_S^X} [h(x) = 1] - \Pr_{x \sim \mathcal{D}_T^X} [h(x) = 1] \right|$$

- The $\mathcal{H}$-divergence relies on the capacity of the hypothesis class $\mathcal{H}$ to distinguish between examples generated by $\mathcal{D}_S^X$ from examples generated by $\mathcal{D}_T^X$.

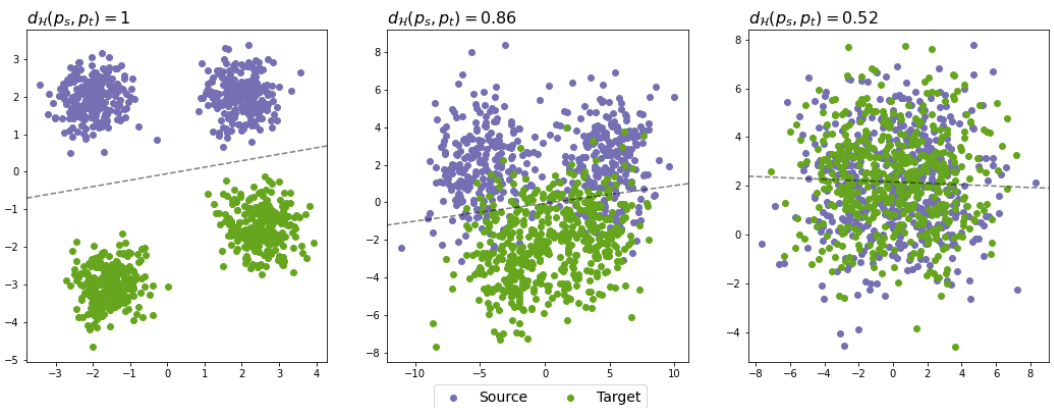


FIGURE – Divergence/discrepancy illustration with linear classifiers. [Richard et al., 2021]

Theoretical setup for domain adaptation

The discrepancy introduced by Ben David et al. 2007, Mansour et al. 2009 measures the availability to discriminate between Source and Target input features distribution.

- Considering two labeling functions f, g and the symmetric loss ℓ over pairs of labels which obeys the triangle inequality.

  The expected loss over any marginal distribution Q is defined by :

$$L_Q(f, g) = \mathbb{E}_Q(\ell(f(X), g(X)))$$

- Consider a hypothesis class $\mathcal{H}$ and
  the marginal distributions S on source domain and T on target domain,
  the discrepancy distance between these two is defined as :

$$\text{disc}_{\mathcal{H},L}(S, T) = \sup_{h,h' \in \mathcal{H}} \left| L_S(h, h') - L_T(h, h') \right|$$

Domain adaptation bound

Mansour et al. 2009 established a bound for the Target risk using the discrepancy :

$$\mathbf{R}_T(h) \leq \mathbf{R}_S(h, h_S^*) + \text{disc}_{\mathcal{H},\ell}(S, T) + \lambda$$

where
$R_Q(h) = \mathbb{E}_Q(\ell(h(X), Y))$,
$R_Q(h, h') = L_Q(h, h') = \mathbb{E}_Q(\ell(h(x), h'(x))), h, h' \in \mathcal{H}$

$h_S^* = \arg\min_{h \in \mathbf{H}} \mathbf{R}_S(h)$, $h_T^* = \arg\min_{h \in \mathcal{H}} \mathbf{R}_T(h)$,
ideal hypothesis for Source and Target domain.

$\lambda = \mathbf{R}_S(h_T^*) + \mathbf{L}_T(h_S^*, h_T^*)$

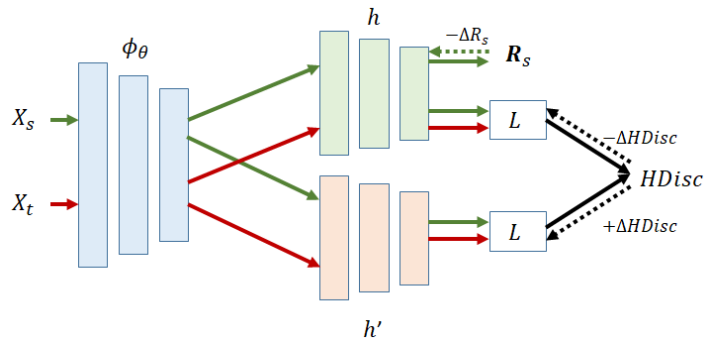
Comments

- **First term :** source risk, can be minimized with source labels
- **Second term :** discrepancy between domains $\rightarrow$ to minimize!
- **Third term :** risk of the ideal hypothesis on the source and target samples. Assumed to be small and not controlled in unsupervised DA.

Hypothesis-Discrepancy Minimization

Minimization of the Hypothesis-Discrepancy Minimization.
For two distributions P, Q over a set $\mathcal{X}$ and for a hypothesis class $\mathcal{H}$ over $\mathcal{X}$, for any $h \in \mathcal{H}$, the hypothesis-discrepancy (or *HDisc*) associated with h is defined as :

$$HDisc_{\mathcal{H},L}(P, Q; h) = \sup_{h' \in \mathcal{H}} \left| \mathop{\mathbb{E}}_{x \sim P}[L(h(x), h'(x))] - \mathop{\mathbb{E}}_{x \sim Q}[L(h(x), h'(x))] \right| \quad (1)$$



with

1. Feature extractor θ $\phi_\theta : \mathcal{X} \to \mathcal{Z}$
2. Hypothesis class $\mathcal{H}_\mathcal{Z} : \mathcal{Z} \to \mathcal{Y}$
3. A labeled source sample $X_S = \{(x_1^{(S)}, ..., x_m^{(S)}\} \in \mathbb{R}^{m \times d}$ with labels $Y_S = \{y_1^{(S)}, ..., y_m^{(S)}\} \in \mathbb{R}^m$
4. Unlabeled target sample $X_T = \{(x_1^{(T)}, ..., x_n^{(T)}\} \in \mathbb{R}^{n \times d}$

Adversarial Hypothesis Discrepancy Minimization

Algorithm

1. $\mathcal{L}_h = \mathbf{R_S}$ updates h to minimize the source loss
2. $\mathcal{L}_{h'} = -HDisc$ updates h' to maximize discrepancy
3. $\mathcal{L}_\theta = HDisc + \mathbf{R_S}$ updates ϕ_θ to minimize discrepancy and source loss

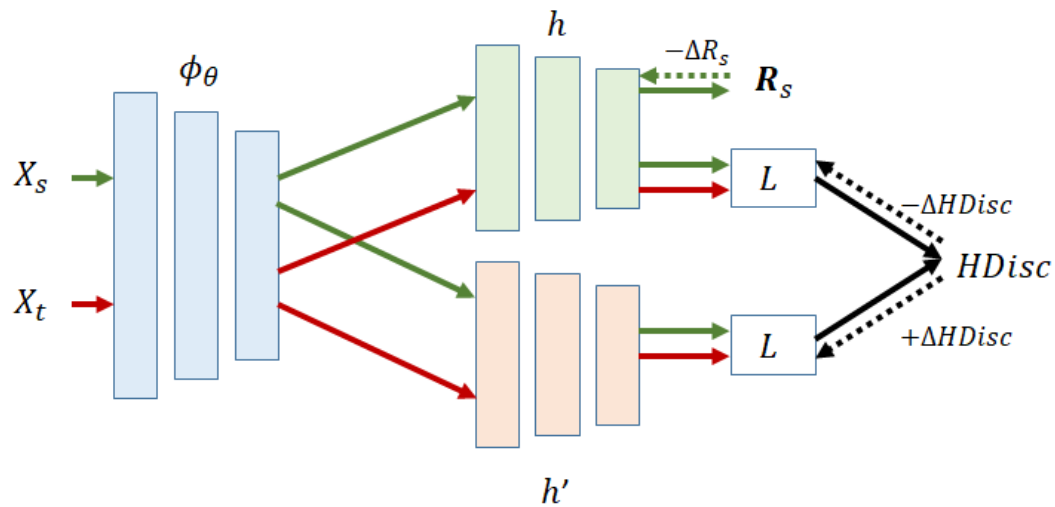


FIGURE – Adversarial Hypothesis Discrepancy Minimization (**AHDM)** using Neural Networks

Adversarial Objective : $\min_{h\in\mathcal{H}} \max_{h'\in\mathcal{H}} \mathbf{R_S}(h) + |\mathbf{L_S}(h,h') - \mathbf{L_T}(h,h')|$

$\min_{\phi_\theta, h\in\mathcal{H}_\mathcal{Z}} \max_{h'\in\mathcal{H}_\mathcal{Z}} \mathbf{R_S}(h\circ\phi_\theta, y_S) + |\mathbf{R_T}(h\circ\phi_\theta, h'\circ\phi_\theta) - \mathbf{R_S}(h\circ\phi_\theta, h'\circ\phi_\theta)|$

Transfer learning
Instance-based

Instance-based TL.

The risk computed on the Target may be related to the risk on the Source domain.

$$
\begin{aligned}
R^{\ell}_{\mathcal{T}}(h) &= \mathop{\mathbb{E}}_{(x,y)\sim\mathcal{T}} \ell(h(x),y) = \int_{(x,y)\in\mathcal{X}\times\mathcal{Y}} \mathcal{T}(x,y)\,\ell(h(x),y)dxdy \\
&= \int_{(x,y)\in\mathcal{X}\times\mathcal{Y}} \frac{\mathcal{T}(x,y)}{\mathcal{S}(x,y)}\mathcal{S}(x,y)\ell(h(x),y)dxdy \\
&= \mathop{\mathbb{E}}_{(x,y)\sim\mathcal{S}} \left[w(x,y)\ell(h(x),y) \right] \\
&= \mathop{\mathbb{E}}_{(x,y)\sim\mathcal{S}} \left[\frac{\mathcal{T}_X(x)\mathcal{T}(y/x)}{\mathcal{S}_X(x)\mathcal{S}(y/x)}\ell(h(x),y) \right]
\end{aligned}
$$

Rem : The support of $\mathcal{T}_X$ is contained in the support of $\mathcal{S}_X$, $\mathcal{S}(x,y) > 0$.

Instance-based TL.

The covariate shift assumption. The predictive dependency remains unchanged between Source and Target while the marginal distributions change.

Covariate shift assumption $\begin{cases} \mathcal{S}(Y/X) = \mathcal{T}(Y/X) \\ \mathcal{T}_{\mathbf{X}}(\mathbf{X}) \neq \mathcal{S}_{\mathbf{X}}(\mathbf{X}) \end{cases}$

$$
\begin{aligned}
R^{\ell}_{\mathcal{T}}(h) &= \mathop{E}_{(x,y)\sim\mathcal{T}} \ell(h(x), y) \\
&= \mathop{E}_{(x,y)\sim\mathcal{S}} \left[\frac{\mathcal{T}_X(x)\mathcal{T}(y/x)}{\mathcal{S}_X(x)\mathcal{S}(y/x)} \right] \ell(h(x), y) \\
&= \mathop{E}_{(x,y)\sim\mathcal{S}} \left[\frac{\mathcal{T}_X(x)}{\mathcal{S}_X(x)} \right] \ell(h(x), y)
\end{aligned}
$$

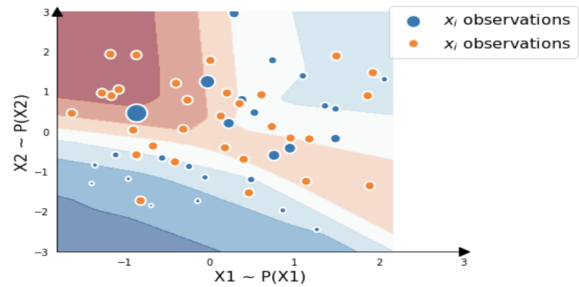

Figure – **Importance Weighting** Source (blue) and target (orange) input samples are drawn according to two different distributions $p_s(x), p_t(x)$. The source samples are reweighted according to the density ratio $w(x) = p_t(x)/p_s(x)$

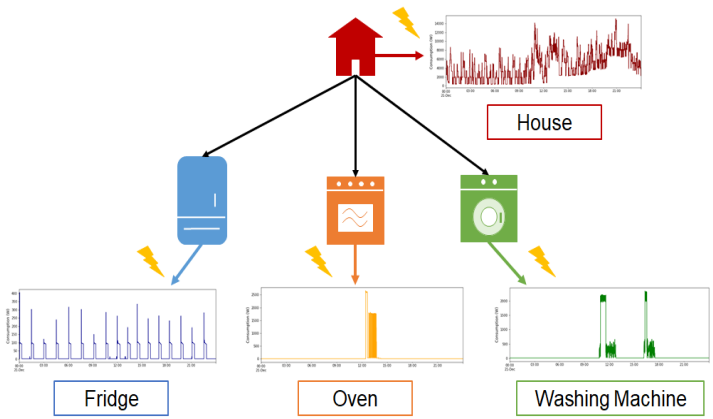
Mixing strategies

Mixing strategies

Unsupervised Multi-source domain adaptation for regression

Application : Non intrusive load monitoring. From the house consumption, estimation of the consumption of an appliance over a period of time.



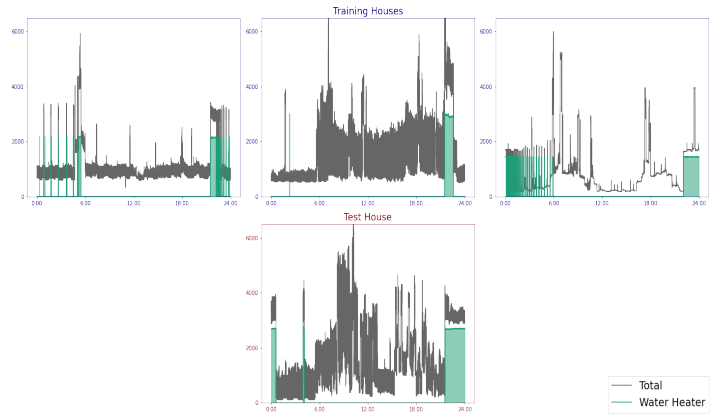


FIGURE – Water heater consumption estimation : input is the whole consumption (gray curve 2s sampling), variable to predict is the whole Water Heater consumption, $y \in \mathbb{R}$ (green area)

Adaptation with Multiple Sources

Unsupervised Multi-source Domain Adaptation.

[Richard et al., 2021]

- K independent source domains $\mathcal{D}_k$ such that $\mathcal{D}_k = \{X_k, f_k\}$ where X_k is the input data with associated marginal distribution $X_k \sim p_k$ and f_k the true labeling function of the domain $(f_k : \mathcal{X} \to \mathcal{Y})$
- A target domain $\mathcal{D}_t = \{X_t, f_t\}$ with $X_t \sim p_t$.
- A labeled source sample $\mathcal{S}_k = \{x_k^i, y_k^i\}$ of size m with an associated empirical probability $\hat{p}_k$ and $y_k^i \in \mathcal{Y}$. Similarly, we consider a unlabeled target sample $\mathcal{S}_t = \{x_t\}$ of size n with an associated empirical probability of $\hat{p}_t$.

How to mix sources ?

We introduce the α-weighted source domain $\mathcal{D}_\alpha = \{p_\alpha, f_\alpha\}$ such that :

- $\alpha \in \Delta = \{\alpha \in \mathbb{R}^K; \alpha_k \geq 0, \sum_{k=1}^K \alpha_k = 1\}$
- $p_\alpha = \sum_{k=1}^K \alpha_k p_k$
- $f_\alpha : x \to (\sum_{k=1}^K \alpha_k p_k(x) f_k(x))/(\sum_{j=1}^K \alpha_j p_j(x))$

[Richard et al., 2021], theoretical guarantees.

Adversarial Learning with HDisc

At a given iteration, four losses are minimized sequentially :

1. $\mathcal{L}_h = \alpha_k \epsilon_k$ updates h to minimize the source loss
2. $\mathcal{L}_{h'} = -HDisc$ updates h' to maximize discrepancy
3. $\mathcal{L}_\theta = HDisc + \sum_{k=1}^{K} \alpha_k \epsilon_k$ updates ϕ_θ to minimize discrepancy and source loss
4. $\mathcal{L}_\alpha = HDisc + \lambda ||\alpha||_2$ updates α to minimize the discrepancy between α-weighted domain and target domain

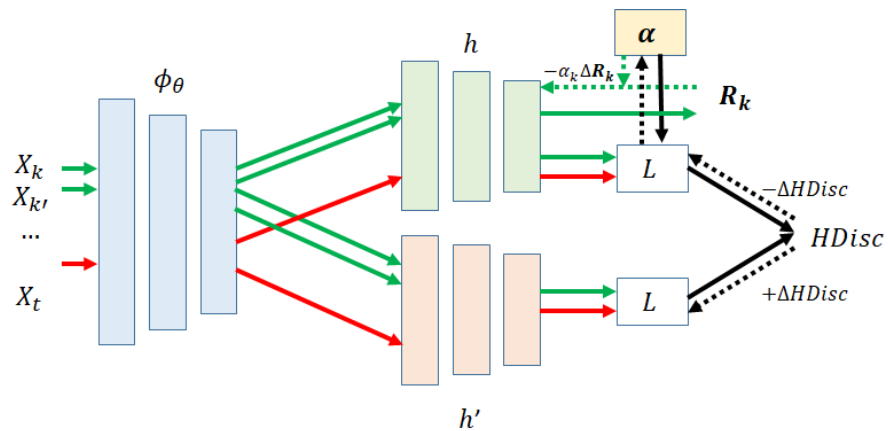

FIGURE – Adversarial Multi-Source Hypothesis Discrepancy Minimization (**AMSHDM)** The adversarial scheme is similar to single-source with weights α. At each iteration, the weights α are updated. Guillaume Richard et al. 2020

Benefits to mix the sources. Application to NILM.
